# Outline

- 1 Review
  - ROC as a Diagnostic Measure
- 2 Covariate Adjustment
  - Normal Noise Assumption
  - General Noise Assumption
  - Nonparametric Smoothing
  - Local Polynomial Regression
  - Bootstrap-based Confidence Bands
  - Simulations
- 3 Example
  - White Onion Data
- 4 Asymptotic Theory and Simulations
  - Asymptotic Results - Normal Error
  - Asymptotic Results - General Error

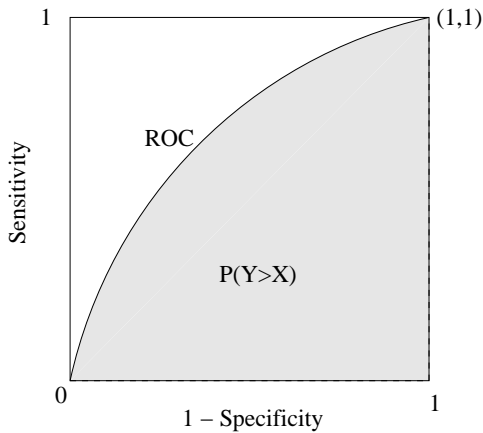

# Diagnostic Tests and ROC

- Consider a test designed to differentiate between two classes: diseased and non-diseased.
- Compared to the truth, a.k.a. "the golden rule", one is interested in determining how well the test is performing.
- Given a certain criterion, one can use it to compare different tests and choose the most effective way of separating the two classes.
- All the information available should be used in assessing the test accuracy.

# ROC

- Suppose that the test result is r.v.  $T$  and depending on whether  $T < c$  or  $T \geq c$  the test result is considered negative, respectively positive.
- **Sensitivity** is the true positive rate.
- **Specificity** is the true negative rate.
- ROC is the plot of Sensitivity against 1-Specificity.
- Different ROC's/tests can be compared using a global univariate summary such as the **area under the curve (AUC)**.
- Bamber (1975) has shown that AUC can be interpreted as the probability that a randomly chosen diseased subject will have a marker (test) value,  $Y$ , greater than the value  $X$  of a randomly chosen nondiseased subject.

## ROC - cont'd

# Separating Populations

- More generally, Wolfe and Hogg (1971) have proposed using the  $P(Y > X)$  as a measure of the difference between two populations and have argued that this is often more meaningful than looking at mean differences.
- Hauck, Hyslop and Anderson (2000) propose the use of  $P(Y > X)$  in assessing treatment effects for clinical trials.

Figure 1.  $\Pr[Y > X]$  when  $X$  is standard normal and  $Y$  is  $N(\mu, \sigma^2)$ .  
Each curve corresponds to a value of  $\mu$ . The ordinate is  $\sigma$ .

- Arises in reliability (Reiser and Guttman, '86).

# ROC - cont'd

- Enormous amount of literature dedicated to constructing/comparing ROC's and estimating AUC's under a wide variety of scenarios (Pepe, 2003).
- For this talk of interest is the extra information available for each unit/individual tested.
- For instance, there may be covariate measurements made for each unit tested.
- **How to incorporate this information in our assessment?**

# ROC & Covariates

**AI** Model the relationship between the ROC/AUC and the covariates directly.

- Loses the connection with the threshold value
- Does not allow prediction of the sensitivity and specificity at a given threshold value conditional on the covariate.
- It does not model covariate effects on the individual marker values.

**AI** Model the covariate effects on the test values and obtain dependence of AUC on covariates via this. (Faraggi, '03).

# A General Regression Model

- The test response variable for nondiseased individuals is  $X$  and for diseased individuals is  $Y$ .

$$X|Z = f(Z) + \sqrt{v_1(Z)} \epsilon_1, \quad (1)$$

$$Y|Z = g(Z) + \sqrt{v_2(Z)} \epsilon_2, \quad (2)$$

- The standardized errors  $\epsilon_1$  and  $\epsilon_2$  are independent of each other with zero mean and unit variance, and the variance functions  $0 < v_1(z) < \infty$  and  $0 < v_2(z) < \infty$  for all  $z \in \mathfrak{R}$ .
- We get a different ROC/AUC for each value of  $Z$ !

# A Simple Illustration

# Normal Noise Assumption

- Errors  $\epsilon_1$  and  $\epsilon_2$  are normally distributed.

$$A_N(z) = P(Y > X | Z = z) = \Phi \left\{ \frac{g(z) - f(z)}{\sqrt{v_1(z) + v_2(z)}} \right\},$$

$$q_N(z) = \Phi \left\{ \frac{g(z) - c}{\sqrt{v_2(z)}} \right\}, \quad 1 - p_N(z) = 1 - \Phi \left\{ \frac{c - f(z)}{\sqrt{v_1(z)}} \right\},$$

for a given threshold  $c$ .

$$q_N(z) = \Phi \left[ \frac{g(z) - f(z) + \sqrt{v_1(z)} \Phi^{-1}\{1 - p_N(z)\}}{\sqrt{v_2(z)}} \right],$$

- The unknown functions  $f, g, v_1, v_2$ , are estimated using nonparametric smoothing.

# General Noise Assumption

- Motivated by the Mann-Whitney statistic:

$$M_{m,n} = \frac{1}{mn} \sum_{i=1}^m \sum_{j=1}^n 1_{[0,\infty)}(y_j - x_i)$$

where  $1_{[0,\infty)}(x) = 1$  if  $x \geq 0$  and  $1_{[0,\infty)}(x) = 0$  otherwise.

- The data for nondiseased and diseased samples is denoted  $\{(z_{i,x}, x_i) : i = 1, \dots, m\}$  and  $\{(z_{j,y}, y_j) : j = 1, \dots, n\}$
- Z values may differ between diseased and non-diseased.**
- We want  $A(z) = P(Y > X | Z = z)$  for any  $z$  in the range of observed values.

# General Noise Assumption - cont'd

- We could use the data corresponding to  $z$ -values in the neighborhood of  $z$ .

$$A_L(z) = \sum_{z_{i,x} \in N(z)} \sum_{z_{j,y} \in N(z)} \frac{1_{[0,\infty)}(y_j - x_i)}{\sum_{i=1}^m 1_{N(z)}(z_{i,x}) \sum_{j=1}^n 1_{N(z)}(z_{j,y})}$$

- We could also use a fully-nonparametric estimator

$$\hat{A}_{FNP} = \frac{\sum_{j=1}^n \sum_{i=1}^m 1_{[0,\infty)}(y_j - x_i) K_{h_1}(Z_j - z) K_{h_2}(Z_i - z)}{\sum_{j=1}^n \sum_{i=1}^m K_{h_1}(Z_j - z) K_{h_2}(Z_i - z)}.$$

- Such local estimators are less efficient and do not take advantage of the model.
- Instead, we propose an estimator that uses the entire data available as well as the models specified.

# General Noise Assumption - cont'd

- If we had all the standardized residuals

$$\epsilon_{i,x} = \frac{x_i - f(z_{i,x})}{\sqrt{v_1(z_{i,x})}}, \quad \epsilon_{j,y} = \frac{y_j - g(z_{j,y})}{\sqrt{v_2(z_{j,y})}},$$

and if we knew  $f, g, v_1, v_2$  then we could construct **working samples**  $\{x_{i,z}, \dots, x_{m,z}\}$  and  $\{y_{1,z}, \dots, y_{n,z}\}$  for  $Z = z$ , as if they were all observed at  $Z = z$ ,

$$x_{i,z} = f(z) + \sqrt{v_1(z)}\epsilon_{i,x}, \quad y_{j,z} = g(z) + \sqrt{v_2(z)}\epsilon_{j,y}.$$

- The Covariate-Adjusted Mann-Whitney Estimator (CAMWE) for  $A(z)$ ,

$$A_M(z) = \frac{1}{mn} \sum_{i=1}^m \sum_{j=1}^n 1_{[0,\infty)}(y_{j,z} - x_{i,z}).$$

## General Noise Assumption - cont'd

- The standardized residuals can be estimated using estimates for  $f$ ,  $g$ ,  $v_1$  and  $v_2$ .
- After obtaining nonparametric estimates of the unknown functions  $f$ ,  $g$ ,  $v_1$  and  $v_2$ , we do not have to choose other tuning parameters for each covariate value  $Z = z$ .
- We can calculate the sensitivity and specificity from the working samples for  $Z = z$ ,

$$q_M(z) = \frac{1}{n} \sum_{j=1}^n 1_{[0,\infty)}(y_{j,z} \geq c), \quad p_M(z) = \frac{1}{m} \sum_{i=1}^m 1_{[0,\infty)}(x_{i,z} \leq c),$$

for a given threshold  $c$ .

- The ROC curves for  $Z = z$  can be obtained by plotting  $q_M(z)$  versus  $1 - p_M(z)$  for all possible values of  $c$ .

# Nonparametric Smoothing Procedures

- Local polynomial regression for estimating  $f$ ,  $g$ ,  $v_1$  and  $v_2$  (Fan and Gijbels, '96).
- The variance functions  $v_1(z)$  and  $v_2(z)$  for heteroscedastic errors are estimated by fitting local polynomial regression to the squared residuals,  $v_{i,x}$  and  $v_{j,y}$ ,  $i = 1, \dots, m, j = 1, \dots, n$ ,

$$v_{i,x} = \{x_i - \hat{f}(z_{i,x})\}^2, \quad v_{j,y} = \{y_j - \hat{g}(z_{j,y})\}^2,$$

- All bandwidths are selected using the standard procedure of leave-one-out cross validation.

# Local Polynomial Regression - short description

- Consider the nondiseased sample  $(z_{i,x}, x_i)$ ,  $i = 1, \dots, m$ , which is assumed to consist of i.i.d. realizations from a random vector  $(Z, X)$ .
- The local polynomial regression estimator of  $f(z)$  is obtained by minimizing

$$\sum_{i=1}^m \left\{ x_i - \sum_{k=0}^p \beta_k (z_{i,x} - z)^k \right\}^2 K_{h_1}(z_{i,x} - z),$$

where  $h_1$  is a bandwidth controlling the amount of smoothing, and  $K_{h_1}(\cdot) = K(\cdot/h_1)/h_1$ .

# Local Polynomial Regression - short description

# Local Polynomial Regression - short description

- In matrix notation let  $Z_x$  be the design matrix

$$Z_x = \begin{pmatrix} 1 & (z_{1,x} - z) & \cdots & (z_{1,x} - z)^p \\ \vdots & \vdots & & \vdots \\ 1 & (z_{m,x} - z) & \cdots & (z_{m,x} - z)^p \end{pmatrix},$$

$W_{x,h_1} = \text{diag}\{K_{h_1}(z_{i,x} - z) : i = 1, \dots, m\}$  and  $\mathbf{x} = (x_1, \dots, x_m)^T$ .

- The local polynomial estimator is given by

$$\hat{f}(z) = \mathbf{e}_1^T (Z_x^T W_{x,h_1} Z_x)^{-1} Z_x W_{x,h_1} \mathbf{x}.$$

- Similarly,

$$\hat{g}(z) = \mathbf{e}_1^T (Z_y^T W_{y,h_2} Z_y)^{-1} Z_y W_{y,h_2} \mathbf{y}.$$

# Local Polynomial Regression - short description

- The nonparametric estimators  $\hat{v}_1(z)$  and  $\hat{v}_2(z)$  are obtained by fitting local polynomial regression to the squared residuals, i.e., the variance observations,  $v_{i,x}$  and  $v_{j,y}$ ,  $i = 1, \dots, m, j = 1, \dots, n$ , defined by

$$v_{i,x} = \{x_i - \hat{f}(z_{i,x})\}^2, \quad v_{j,y} = \{y_j - \hat{g}(z_{j,y})\}^2.$$

- Let  $b_1$  be the bandwidth for  $\hat{v}_1(z)$ . Let  $\mathbf{v}_x = (v_{1,x}, \dots, v_{m,x})^T$ . Then

$$\hat{v}_1(z) = \mathbf{e}_1^T (Z_x^T W_{x,b_1} Z_x)^{-1} Z_x W_{x,b_1} \mathbf{v}_x$$

where  $W_{x,b_1} = \text{diag}\{K_{b_1}(z_{i,x} - z) : i = 1, \dots, m\}$ .

- Similar calculations can be done for  $\hat{v}_2$ .

# Bootstrap-based Confidence Bands

- Sample with replacement from the estimated standardized residuals  $\{\hat{\epsilon}_{i,x} : i = 1, \dots, m\}$  and  $\{\hat{\epsilon}_{j,y} : j = 1, \dots, n\}$  to form bootstrap sets  $\{\hat{\epsilon}_{i,x}^{(b)}; i = 1, \dots, m\}$  and  $\{\hat{\epsilon}_{j,y}^{(b)} : j = 1, \dots, n\}$ .
- Using the estimated mean and variance functions from the observed data, construct the bootstrapped working samples at covariate value  $Z = z$ ,

$$\hat{x}_{i,z}^{(b)} = \hat{f}(z) + \hat{\epsilon}_{i,x}^{(b)} \sqrt{\hat{v}_1(z)}, \quad \hat{y}_{j,y}^{(b)} = \hat{g}(z) + \hat{\epsilon}_{j,y}^{(b)} \sqrt{\hat{v}_2(z)}, \quad i = 1, \dots, m,$$

- Estimate  $A^{(b)}(z)$  using

$$\hat{A}_M^{(b)}(z) = \frac{1}{mn} \sum_{i=1}^m \sum_{j=1}^n 1_{[0,\infty)}(\hat{y}_{j,y}^{(b)} - \hat{x}_{i,x}^{(b)}).$$

Then the set  $\{\hat{A}_M^{(b)}(z) : b = 1, \dots, B\}$  is used to obtain confidence limits for  $\hat{A}(z)$ .

# Simulations

- For non-diseased individuals:

$$X_i = \alpha_0 + \alpha_1 Z_i + \alpha_2 \sin(Z_i) + \epsilon_i$$

where the Student(3) deviate  $\epsilon$  has conditional variance rescaled by  $x_{i0} + \xi_1 \Phi(\delta_0 + \delta_1 Z_i)$ .

- For diseased individuals we consider the model

$$Y_i = \beta_0 + \beta_1 Z_i + \beta_2 \sin(Z_i) + \beta_3 \sqrt{Z_i - 1} + \eta_i,$$

with  $\eta$  Student(3) with conditional variance  $\text{var}(\eta_i | Z_i) = \text{var}(\epsilon_i | Z_i) + \gamma$ .

# Simulations-cont'd

Scenario 1:  $n = 40$ ,  $\beta_0 = \alpha_0 = 0$ ,  $\alpha_1 = \alpha_2 = \beta_2 = \beta_1 = 3$ ,  $\beta_3 = 1$   
 $\xi_0 = 0.3$ ,  $\xi = 3$ ,  $\delta_1 = 2$ ,  $\delta_0 = -6$ ,  $\gamma = 1.2$

# Simulations-cont'd

Scenario 2:  $n = 100$ ,  $\beta_0 = \alpha_0 = 0$ ,  $\alpha_1 = \alpha_2 = \beta_2 = \beta_1 = 1.5$ ,  $\beta_3 = 2.5$   
 $\xi_0 = 0.3$ ,  $\xi = 1$ ,  $\delta_1 = 2$ ,  $\delta_0 = -6$ ,  $\gamma = 1.2$

# Simulations-cont'd

Confidence Bands for errors distributed: normal (L),  $t_3$  (C) and lognormal (R)

# Example: White Onions Data

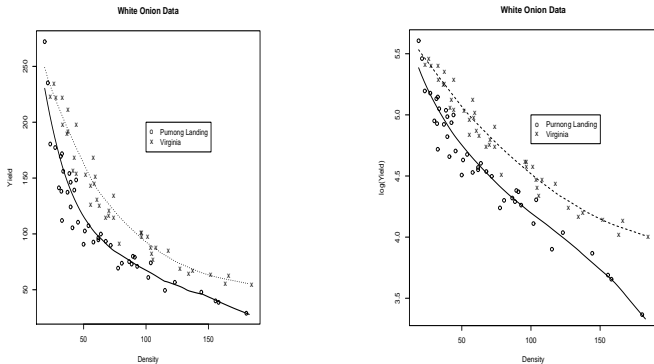

Figure: Spanish Onion Data with response on: the original scale (left) the logarithmic scale (right).

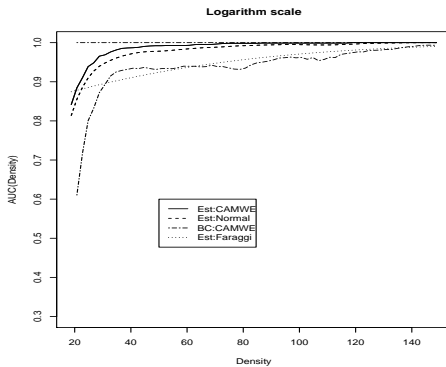

# Example

**Figure:** Comparison of estimated dependency between AUC and density obtained using the nonparametric approach with and without normal noise with the parametric estimation of the same dependency assuming a normal linear regression model.

# Example

Figure: *Response is on the logarithmic scale.*

# Asymptotic Results - Normal Error

## Convergence in the Normal Error Case

If  $n/m \rightarrow \infty$ ,

$$\sqrt{mh_1}(\hat{A}_N(z) - A_N(z)) \rightarrow N(B_1(z), V_1(z)).$$

If  $n/m \rightarrow 0$ ,

$$\sqrt{nh_2}(\hat{A}_N(z) - A_N(z)) \rightarrow N(B_2(z), V_2(z)).$$

If  $n/m \rightarrow c \in (0, \infty)$ ,

$$\sqrt{mh_1}(\hat{A}_N(z) - A_N(z)) \rightarrow N(B_3(z), V_3(z)).$$

Under stronger assumptions the convergence of  $\hat{A}_N(z) - A_N(z)$  to 0 holds almost surely.

# Asymptotic Results - General Error

## Step I - Convergence of the hypothetical estimator

Take

$$A_M(z) = \frac{1}{mn} \sum_{i=1}^m \sum_{j=1}^n 1_{[0, \infty)}(y_{j,z} - x_{i,z})$$

where

$$x_{i,z} = f(z) + \sqrt{v_1(z)}\epsilon_{i,x}, \quad y_{j,z} = g(z) + \sqrt{v_2(z)}\epsilon_{j,y}.$$

Then if  $n/m \rightarrow \lambda$  for some  $0 < \lambda < \infty$ ,  $\xi(z) > 0$

$$\sqrt{m+n}\{A_M(z) - A(z)\} \xrightarrow{D} N(0, \xi(z))$$

where  $\lambda^* = 1/(1 + \lambda)$ .

# Asymptotic Results - General Error

## Step II - $L^2$ Consistency

For a given  $z$

$$E[\{\hat{A}_M(z) - A_M(z)\}^2] \longrightarrow 0.$$

## Step I + Step II

$$E[\{\hat{A}_M(z) - A(z)\}^2] \longrightarrow 0.$$
