Parametric models and likelihood

- model $f(y; \theta)$,
- data $y = (y_1, \dots, y_n)$
- log-likelihood function
- parameter of interest

- likelihood inference

$$\theta \in \mathbb{R}^p$$

independent observations

$$\ell(\theta; y) = \log f(y; \theta)$$

$$\theta = (\psi, \lambda), \quad \psi \in \mathbb{R}^d$$

$$w(\psi) = 2\{\ell(\hat{\psi}, \hat{\lambda}) - \ell(\psi, \hat{\lambda}_\psi)\} \sim \chi_d^2$$

$$w_B(\psi) = \frac{w(\psi)}{1 + B(\psi)} \sim \chi_d^2 \quad O_p(n^{-2})$$
$$B(\psi) = E\{w(\psi)\}/d$$

$$w^*(\psi) = w(\psi) \left\{ 1 - \frac{\log \gamma(\psi)}{w(\psi)} \right\}$$

Skovgaard, 2001

Example: 2×3 contingency table

- activity amongst psychiatric patients

Everitt, 1992

	Affective disorders	Schizophrenics	Neurotics
Retarded	12	13	5
Not retarded	18	17	25

- model: log-linear $y \sim \text{Poisson}$, $\log\{E(y)\} = X\theta$, $\theta \in \mathbb{R}^6$
- log-likelihood $\ell(\theta; y) = \theta^T X^T y - 1^T e^{X\theta} = \theta^T s - c(\theta)$
- $\theta = (\psi, \lambda)$ $\psi \in \mathbb{R}^2, \lambda \in \mathbb{R}^4$
- (ψ_1, ψ_2) interaction parameters
- $H_0 : \psi = \psi_0 = (0, 0)$ independence
- log-likelihood $\ell(\psi, \lambda; y) = \psi^T s_1 + \lambda^T s_2 - c(\psi, \lambda)$

Testing $\psi = 0$

$$w(\psi_0) \sim \chi_2^2 \quad p\text{-value } 0.047$$

$$w^*(\psi_0) \quad p\text{-value } 0.048$$

$$\text{directional} \quad p\text{-value } 0.050$$

$$\text{exact} \quad p\text{-value } 0.051$$

Linear exponential families

- model $f(y; \theta) = \exp[\varphi(\theta)^T s(y) - c\{\varphi(\theta)\} - d(y)]$ y_1, \dots, y_n i.i.d
- sufficient statistic $s(y)$

$$f(s; \theta) = \exp[\varphi(\theta)^T s - nc\{\varphi(\theta)\} - \tilde{d}(s)] = \int_{\{y: s(y)=s\}} f(y; \theta) dy$$

- reduce dimension from n to p by marginalization
- linear parameter of interest $\varphi(\theta) = \theta = (\psi, \lambda)$
- model $f(s_1, s_2; \psi, \lambda) = \exp\{\psi^T s_1 + \lambda^T s_2 - nc(\psi, \lambda) - \tilde{d}(s)\}$
- conditional density $f(s_1 | s_2; \psi) = \exp\{\psi^T s_1 - n\tilde{c}_2(\psi) - \tilde{d}_2(s_1)\}$
- reduce dimension from p to d by conditioning

... conditional density

- $f(\mathbf{s}_1 \mid \mathbf{s}_2; \boldsymbol{\psi}) = \exp\{\boldsymbol{\psi}^T \mathbf{s}_1 - n\tilde{c}_2(\boldsymbol{\psi}) - \tilde{d}_2(\mathbf{s}_1)\}$ $\theta = (\boldsymbol{\psi}, \lambda)$
- $f(\mathbf{s}_1 \mid \mathbf{s}_2; \boldsymbol{\psi}) = \frac{f(\mathbf{s}_1, \mathbf{s}_2; \boldsymbol{\psi}, \lambda)}{f(\mathbf{s}_2; \boldsymbol{\psi}, \lambda)} \propto f(\mathbf{s}; \boldsymbol{\psi}, \lambda)$ with \mathbf{s}_2 held fixed
- \mathbf{s}_2 held fixed $\iff \hat{\lambda}_{\boldsymbol{\psi}}$ held fixed $\hat{\theta}_{\boldsymbol{\psi}} = (\boldsymbol{\psi}, \hat{\lambda}_{\boldsymbol{\psi}})$
- saddlepoint approximation:
 $f(\mathbf{s}_1 \mid \mathbf{s}_2; \boldsymbol{\psi}) \doteq c \exp[\ell(\hat{\theta}_{\boldsymbol{\psi}}^0; \mathbf{s}) - \ell\{\hat{\theta}(\mathbf{s}); \mathbf{s}\}] |j\{\hat{\theta}(\mathbf{s}); \mathbf{s}\}|^{-1/2}, \quad \mathbf{s} \in L_{\boldsymbol{\psi}}^0$
- plane $L_{\boldsymbol{\psi}}^0 = \{\mathbf{s} \in \mathbb{R}^p : \hat{\lambda}_{\boldsymbol{\psi}} = \hat{\lambda}_{\boldsymbol{\psi}^0}\} = \{\mathbf{s} \in \mathbb{R}^p : \mathbf{s}_2 = \mathbf{s}_2^0\}$
- $\hat{\theta}(\mathbf{s}) : \partial \ell(\theta; \mathbf{s}) / \partial \theta = 0$ m.l.e. as a function of the variable
- log-likelihood function $\ell(\theta; \mathbf{s}) = \boldsymbol{\psi}^T \mathbf{s}_1 + \lambda^T \mathbf{s}_2 - c(\theta), \quad \mathbf{s} \in L_{\boldsymbol{\psi}}^0$

... conditional density

$$f(\mathbf{s}_1 \mid \mathbf{s}_2; \psi) \doteq c \exp[\ell(\hat{\theta}_{\psi}^0; \mathbf{s}) - \ell\{\hat{\theta}(\mathbf{s}); \mathbf{s}\}] |j\{\hat{\theta}(\mathbf{s}); \mathbf{s}\}|^{-1/2}, \quad \mathbf{s} \in L_{\psi}^0$$

	Affective disorders	Schizophrenics	Neurotics
Retarded	12	13	5
Not retarded	18	17	25

$$\mathbf{s}_1 \in \mathbb{R}^2, \mathbf{s}_2 \in \mathbb{R}^4$$

L_{ψ}^0 : all 2×3 tables with the same row and column totals

Directional tests

- measure the **directed departure** from H_0 in L_ψ^0
- s_ψ : expected value of s_1 , under H_0
- s^0 : observed value of s_1 = 0 from centering
- L_ψ^* : line through these two points
- $L_\psi^* = ts^0 + (1 - t)(s_\psi - s^0)$, $t \in \mathbb{R}$

... directional tests

$$L_{\psi}^* = ts^0 + (1 - t)s_{\psi}$$

○ null hypothesis of independence $t = 0$
 X observed value of s $t = 1$

p -value compares probability from \times to ∞ to that from \circ to ∞
 along the line in the sample space curve in the parameter space

like a 2-sided p -value $\Pr(\text{response} > \text{observed} \mid \text{response} > 0)$

... directional p -value

- $p\text{-value} = \frac{\int_1^\infty t^{d-1} f\{s(t); \psi\} dt}{\int_0^\infty t^{d-1} f\{s(t); \psi\} dt}$ $s(t)$ along the line L_ψ^*

- t^{d-1} from change to polar coordinates $\|s\|$, conditional on $s/\|s\|$

- Simplifications:

- 1: $L_\psi^* \subset L_\psi^0 \subset \mathbb{R}^p$

- 2: ratio of two integrals – drop any terms that don't depend on t

- 3: saddlepoint approximation

$$f(s; \psi) \doteq c \exp[\ell(\hat{\theta}_\psi^0; s) - \ell\{\hat{\theta}(s); s\}] |j\{\hat{\theta}(s); s\}|^{-1/2}, \quad s \in L_\psi^0$$

$$h(t) = f\{s(t); \psi\}$$

2×3 table

$$t = 0$$

10	10	10
20	20	20

$$t = 0.5$$

Simulations

3 groups, 5 observations per group

Simulations

1000 groups, 5 observations per group

dimension ψ 999; dimension nuisance 1001

Example: covariance selection

- model $y_i \sim N_q(\mu, \Lambda^{-1})$ inverse covariance matrix

- linear exponential family

$$\ell(\theta; \mathbf{y}) = \frac{n}{2} \log |\Lambda| - \frac{1}{2} \text{tr}(\Lambda \mathbf{y}^T \mathbf{y}) + \mathbf{1}^T \mathbf{y} \xi - \frac{n}{2} \xi^T \Lambda \xi \quad \mathbf{s}_1, \mathbf{s}_2$$

- $\theta = (\xi, \Lambda) = (\Lambda \mu, \Lambda)$

- H_0 : some off-diagonal elements of Λ are 0

$$\psi_1 = \dots = \psi_d = 0$$

conditional independence

- need constrained m.l.e: use `fitConGraph` in `ggm`

- $\hat{\Lambda}^{-1}(t) = t \hat{\Lambda}^{-1} + (1 - t) \hat{\Lambda}_0^{-1}$

m.l.e. along the line

- $f\{\mathbf{s}(t); \psi\} \propto |t \hat{\Lambda}^{-1} + (1 - t) \hat{\Lambda}_0^{-1}|^{(n-q-2)/2}$

... covariance selection

Covariance matrix 11×11 ; dimension of $\psi = 45$

first order Markov dependence

Tangent exponential model $n \downarrow p$ (dimension of y to dimension of θ)

- Every model $f(y; \theta)$ on \mathbb{R}^n can be approximated by an exponential family model:

$$f_{TEM}(s; \theta) ds = \exp\{\varphi(\theta)^T s + \ell(\theta)\} f_0(s) ds$$

- s is a score variable on \mathbb{R}^p $s(y) = -\ell_\varphi(\hat{\theta}^0; y)$
- $\ell(\theta) = \ell(\theta; y^0)$ is the observed log-likelihood function
- $\varphi(\theta) = \varphi(\theta; y^0)$ is the canonical parameter $\in \mathbb{R}^p$
to be described
- matches log-likelihood function at y^0 , and its first derivative on the sample space, at y^0 by construction
- implements conditioning on an approximate ancillary statistic
contrast with exp fam

Aside: canonical parameter $\varphi(\theta)$

- if $f(y; \theta)$ is an exponential family, φ is sitting in the model
- if not find a **pivotal quantity** $z_i = z_i(y_i; \theta)$ with a fixed distribution

example: $(y_i - \mu)/\sigma$

- define $V_i = - \left(\frac{\partial z_i}{\partial y_i} \right)^{-1} \frac{\partial z_i}{\partial \theta} \Big|_{y=y^0, \theta=\hat{\theta}^0}$ a vector of length p

$$\varphi(\theta) = \varphi(\theta; y^0) = \sum_{i=1}^n \frac{\partial \ell(\theta; y^0)}{\partial y_i} V_i = \ell_{;V}(\theta; y^0)$$

Testing a value for ψ

eliminating nuisance parameter: $p \downarrow d$

- $\theta = (\psi, \lambda)$; $\varphi = \varphi(\theta)$ is the canonical parameter of the TEM
- with ψ fixed by the hypothesis, we can integrate out the nuisance parameter by **Laplace approximation**
- define the same plane in the score space L_ψ^0 , where $\hat{\varphi}_\psi$ is fixed at its observed value

$$f(\mathbf{s}; \psi) = \mathbf{c} \exp\{\ell(\hat{\varphi}_\psi^0; \mathbf{s}) - \ell(\hat{\varphi}(\mathbf{s}); \mathbf{s})\} |j_{\varphi\varphi}(\hat{\varphi}(\mathbf{s}); \mathbf{s})|^{-1/2} |j_{(\lambda\lambda)}(\hat{\varphi}_\psi^0; \mathbf{s})|^{1/2}$$
$$\mathbf{s} \in L_\psi^0$$

$$p\text{-value} = \frac{\int_1^\infty t^{d-1} f\{\mathbf{s}(t); \psi\} dt}{\int_0^\infty t^{d-1} f\{\mathbf{s}(t); \psi\} dt}$$

$\mathbf{s}(t)$ along the line L_ψ^*

Example: marginal independence

- $y_i \sim N_q(\mu, \Sigma)$, H_0 : some entries of Σ are 0
- estimate Σ under H_0 using `fitCovGraph`
- $\ell(\Sigma) = \frac{n-1}{2} [\log |\varphi(\Sigma)| - \frac{n-1}{2} \text{tr} \{ \varphi(\Sigma) \mathbf{S} \}]$, $\varphi(\Sigma) = \Sigma^{-1}$
 $S = \text{sample covariance}$
- $f\{\mathbf{s}(t); \psi\} \propto |t\hat{\Sigma} + (1-t)\hat{\Sigma}_0|^{(n-q-2)/2} |j_{(\lambda\lambda)}\{\hat{\Sigma}_0; \mathbf{s}(t)\}|^{1/2}$
- $j_{(\lambda\lambda)}$ needs $\partial\ell(\Sigma)/\partial(\sigma_{jk})$ for the non-zero elements
- $j_{\lambda_j\lambda_k}\{\hat{\Sigma}_0; \mathbf{s}(t)\} = \frac{n-1}{2} \left(\text{tr}(\mathbf{A}_{kj} + t \left[\text{tr}\{(\mathbf{A}_{kj} + \mathbf{A}_{jk})(\hat{\Sigma}_0^{-1}\hat{\Sigma} - I_q)\}\right] \right)$
- $\mathbf{A}_{kj} = \Sigma_0^{-1}(\partial\Sigma/\partial\lambda_k)\Sigma_0^{-1}(\partial\Sigma/\partial\lambda_j)$

... independence

Conclusion

- different way to assess vector parameters
- incorporates information in the direction of departure
- easy to compute: two model fits, plus 1-d numerical integration
- accurate conditionally, by construction, and unconditionally
simulations
- can be used in models of practical interest
- exponential family model not necessary – easily generalized using approximate exponential family model
