1. (a) (4 points) State the simple linear regression model in matrix terms, defining all matrices and vectors. Include the Gauss-Markov assumptions.

\[ Y = X\beta + \epsilon \] (1 mark)

where

\[ Y = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix}, \quad X = \begin{bmatrix} 1 & X_1 \\ 1 & X_2 \\ \vdots & \vdots \\ 1 & X_n \end{bmatrix}, \quad \beta = \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix}, \quad \epsilon = \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix} \] (1 mark)

Gauss-Markov assumptions: (2 marks)

- \( \text{E}(\epsilon) = 0 \)
- \( \text{Cov}(\epsilon) = \sigma^2 I \)

(b) (4 points) Use matrix properties to prove \( e'\bar{Y} = 0 \) where \( e \) is the vector of residuals and \( \bar{Y} \) is the vector of predicted values. (Do not work with the individual elements of these matrices.)

\[
e'\bar{Y} = [(I - H)Y]'HY
= Y'(I - H)HY
= Y'HY - Y'H^2Y
= Y'HY - Y'HY
= 0
\]
2. The times to failure \((Y)\) for 20 light bulbs were measured at 20 temperatures \((X)\). A simple linear regression was carried out to explore how the failure time is related to the temperature.

(a) (5 points) Here are some calculated values from the 20 data points.

\[
(X'X)^{-1} = \begin{pmatrix}
0.105 & -0.0136 \\
-0.0136 & 0.00335
\end{pmatrix}
\]
\[
X'Y = \begin{pmatrix}
367.9 \\
965.6
\end{pmatrix}
\]
\[
e'e = 789.7
\]

What are the estimated slope and intercept of the regression line and their estimated standard errors?

\[
b = (X'X)^{-1}X'Y
\]
\[
= \begin{pmatrix}
.105 & -0.0136 \\
-0.0136 & .00335
\end{pmatrix}
\begin{pmatrix}
367.9 \\
965.5
\end{pmatrix}
\]
\[
= \begin{pmatrix}
25.5 \\
-1.77
\end{pmatrix}
\]

So estimated intercept is 25.5 and estimated slope is -1.77. (2 marks)

\[
\text{Cov}(b) = \sigma^2(X'X)^{-1}
\]

\textit{Estimate of } \sigma^2: s^2 = \frac{\mathbf{e}'\mathbf{e}}{n-2} = \frac{789.7}{18} = 43.9 \ (1 \text{ mark})
\text{ s.e. of } b_0 = \sqrt{43.9(1.05)} = 2.15 \ (1 \text{ mark})
\text{ s.e. of } b_1 = \sqrt{43.9(0.00335)} = .38 \ (1 \text{ mark})
(b) (2 points) A scatterplot and a plot of the residuals versus the predicted values for the light bulb problem are given below. What additional information does this provide?

The point on the far right in the scatterplot and the far left in the residual plot is influential. (1 mark) The linear model may only be appropriate for temperatures less than $10^\circ$. (1 mark)
3. An experiment was performed to determine which temperature in the manufacturing process results in the strongest product. In analysing the data, it was determined that a straight line model was an appropriate fit for the regression with square root of strength (sqrtstrn) as the dependent variable and temperature (temp) as the independent variable. Six temperatures (80° to 180° in increments of 20°) were tested five times, resulting in 30 data points. Some SAS output is given below.

</table>

(a) (6 points) Construct simultaneous 90% confidence intervals for the expected strength for temperatures of 80° and 180°. Use the Bonferroni method.

When temp is 80, predicted value of sqrtstrn is 44.79 + 4.953(80) = 441.03
When temp is 180, predicted value of sqrtstrn is 44.79 + 4.953(180) = 936.33

(1 mark each)

Critical value: \( t_{28, .025} = 2.048 \) (1 mark)

CI for \( E(\text{sqrtstrn}) \) when temp is 80: (2 marks)

\[
441.03 \pm 2.048 \sqrt{92.36 \left( \frac{1}{10} + \frac{(80-130)^2}{20(1206.89)} \right)} = 441.03 \pm 6.37 = (434.66, 447.4)
\]

CI for \( E(\text{sqrtstrn}) \) when temp is 180:

\(936.33 \pm 6.37 = (929.96, 942.7)\) (1 mark)
(b) (2 points) The Bonferroni method is “conservative”. Explain what this means in relation to your answer to (a).

The probability that both CIs constructed in the manner in (a) capture the true expected strengths is at least 90% (probably more). (1 mark for each concept indicated by bold words)

(c) (3 points) Before carrying out the regression using the square root of strength, a regression was first carried out with the raw data (strength regressed on temperature). What would be evident in the plot of residuals versus predicted values that would cause the people analysing the data to try the square root transform?

(Wording of question has been corrected for answer below.)

curvature (1 mark)
non-constant variance (1 mark)

For the other mark, needed to note either that the curvature is monotone or the variance increases linearly in the mean value of Y.
(d) (4 points) The normal probability plot of the residuals for the regression of square root of strength on temperature is given below. What additional information does this give you? Quote one number from the SAS output whose value is relevant to this additional information and explain how it is relevant.

(Wording of question has been corrected for answer below.)

The errors do not follow a normal distribution. (1 mark)
The distribution of the residuals has heavier tails than a normal distribution. (1 mark)
You could pick any of the 3 p-values from the output. (1 mark)
The p-value may not be accurate as the relevant test statistic won't actually have an F (or t) distribution. (1 mark)
